Solution to Homework 18

- One step in learning to read IA32 code is to become very familiar with the way arguments are passed on the stack. The key to solving this problem is to note that the storage of `d` at `p` is implemented by the instruction at line 3 of the assembly code, from which you work backward to determine the types and positions of arguments `d` and `p`. Similarly, the subtraction is performed at line 6, and from this you can work backward to determine the types and positions of arguments `x` and `c`. The following is the function prototype:

```
int fun(short c, char d, int *p, int x);
```

- `0x80003C`
 - `0x800014`
 - `x` at `0x800038`; `y` at `0x800034`
 -

0x80003C	0x800060	← %ebp
0x800038	0x53	x
0x800034	0x46	y
0x800030		
0x80002C		
0x800028		
0x800024		
0x800020		
0x80001C	0x800038	
0x800018	0x800034	
0x800014	0x300070	← %esp

E. Byte addresses `0x800020` through `0x800033` are unused.

- Registers `%edi`, `%esi`, and `%ebx` are callee-save. The procedure must save them on the stack before altering their values and restore them before returning. The other three registers, `%eax`, `%ecx`, and `%edx`, are caller-save. They can be altered without affecting the behavior of the caller.

- **Welcome: Sean**
